DFA \leftarrow ϵ -NFA (Subset Construction)

Let's consider **ϵ -transitions** which can be taken **without consuming any input symbol** in finite automata.

For example, the following automaton has an **ϵ -transition** from q_2 to q_0 :

Then, the above automaton **accepts** the following words:

ab abab ababab ...

Let's formally define **ϵ -NFA**, an extension of NFA with ϵ - transitions.

Definition of ϵ -NFA

Definition (ϵ -Nondeterministic Finite Automaton (ϵ -NFA))

An **ϵ -nondeterministic finite automaton** is a 5-tuple:

$$N^\epsilon = (Q, \Sigma, \delta, q_0, F)$$

- Q is a finite set of **states**
- Σ is a finite set of **symbols**
- $\delta : Q \times (\Sigma \cup \{\epsilon\}) \rightarrow \mathcal{P}(Q)$ is the **transition function**
- $q_0 \in Q$ is the **initial state**
- $F \subseteq Q$ is the set of **final states**

$$N_1^\epsilon = (\{q_0, q_1, q_2\}, \{a, b\}, \delta, q_0, \{q_2\})$$

$$\delta(q_0, a) = \{q_1\}$$

$$\delta(q_1, a) = \emptyset$$

$$\delta(q_2, a) = \emptyset$$

$$\delta(q_0, b) = \emptyset$$

$$\delta(q_1, b) = \{q_2\}$$

$$\delta(q_2, b) = \emptyset$$

$$\delta(q_0, \epsilon) = \emptyset$$

$$\delta(q_1, \epsilon) = \emptyset$$

$$\delta(q_2, \epsilon) = \{q_0\}$$

Definition of ϵ -NFA

```
// The definition of epsilon-NFA
case class ENFA(
    states: Set[State],
    symbols: Set[Symbol],
    trans: Map[(State, Option[Symbol]), Set[State]],
    initState: State,
    finalStates: Set[State],
)
```

```
// An example of epsilon-NFA
val enfa1: ENFA = ENFA(
    states = Set(0, 1, 2),
    symbols = Set('a', 'b'),
    trans = Map(
        (0, Some('a')) -> Set(1),      // (0, a) -> 1
        (1, Some('b')) -> Set(2),      // (1, b) -> 2
        (2, None)       -> Set(0),      // (2, ε) -> 0
    ).withDefaultValue(Set()),
    initState    = 0,
    finalStates  = Set(2),
)
```

$$N_1^\epsilon = (\{q_0, q_1, q_2\}, \{a, b\}, \delta, q_0, \{q_2\})$$

$$\delta(q_0, a) = \{q_1\}$$

$$\delta(q_1, a) = \emptyset$$

$$\delta(q_2, a) = \emptyset$$

$$\delta(q_0, b) = \emptyset$$

$$\delta(q_1, b) = \{q_2\}$$

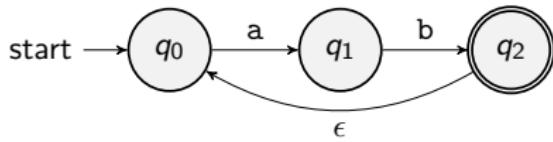

$$\delta(q_2, b) = \emptyset$$

$$\delta(q_0, \epsilon) = \emptyset$$

$$\delta(q_1, \epsilon) = \emptyset$$

$$\delta(q_2, \epsilon) = \{q_0\}$$

Transition Diagram

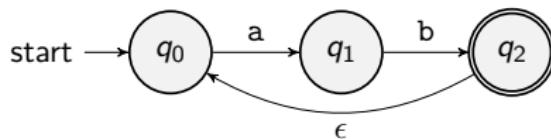

Transition Table

q	a	b	ε
→ q0	{q1}	∅	∅
q1	∅	{q2}	∅
*q2	∅	∅	{q0}

Definition (ϵ -Closures)

The **ϵ -closure** $\text{EClo}(q)$ for a state q is the set of all reachable states only through ϵ -transitions from q , and it can be inductively defined as:

- **(Basis Case)** $q \in \text{EClo}(q)$
- **(Induction Case)** $(q' \in \delta(q, \epsilon) \wedge q'' \in \text{EClo}(q')) \Rightarrow q'' \in \text{EClo}(q)$

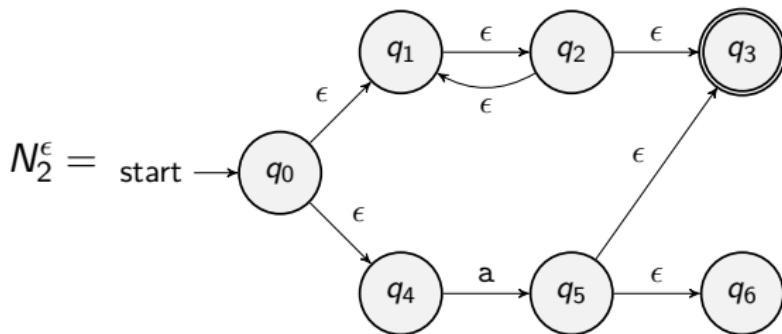

$$\text{EClo}(q_2) = \{q_0, q_2\}$$

We sometimes need to define the ϵ -closure for a **set of states** $S \subseteq Q$:

$$\forall S \subseteq Q. \text{EClo}(S) = \bigcup_{q \in S} \text{EClo}(q)$$

ϵ -Closures – Example

$$\text{Eclo}(q_0) = \{q_0, q_1, q_2, q_3, q_4\}$$

$$\text{Eclo}(q_2) = \{q_1, q_2, q_3\}$$

$$\text{Eclo}(q_5) = \{q_3, q_5, q_6\}$$

$$\begin{aligned}\text{Eclo}(\{q_2, q_5\}) &= \text{Eclo}(q_2) \cup \text{Eclo}(q_5) \\ &= \{q_1, q_2, q_3\} \cup \{q_3, q_5, q_6\} \\ &= \{q_1, q_2, q_3, q_5, q_6\}\end{aligned}$$

Then, how to implement the `eclo` method for ϵ -closure?

```
case class ENFA(...):
    ...
    // The epsilon-closure of a state
    def eclo(q: State): Set[State] = ???

    // The epsilon-closure of a set of states
    def eclo(qs: Set[State]): Set[State] = qs.flatMap(eclo)
```

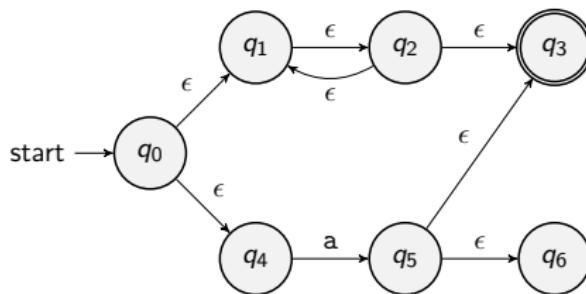

The ϵ -closures for states 0, 2, 5, and $\{2, 5\}$ are as follows:

```
// Another example of epsilon-NFA
val enfa2: ENFA = ENFA(...)
enfa2.eclo(0)          // Set(0, 1, 2, 3, 4)
enfa2.eclo(2)          // Set(1, 2, 3)
enfa2.eclo(5)          // Set(3, 5, 6)
enfa2.eclo(Set(2, 5)) // Set(1, 2, 3, 5, 6)
```

```
case class ENFA(...):  
...  
// The epsilon-closure of a state  
def wrongEClo(q: State): Set[State] =  
    val basis = Set(q)                                // Basis Case  
    val induc = enfa.trans(q, None).flatMap(wrongEClo) // Induction Case  
    basis ++ induc
```

The above implementation is **WRONG** because of **infinite loop**:

```
enfa2.wrongEClo(5) // Set(3, 5, 6)  
enfa2.wrongEClo(2) // INFINITE LOOP -- cycle between states 1 and 2
```

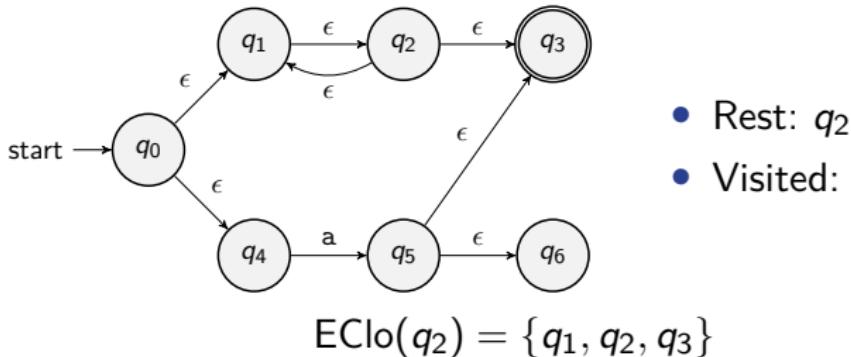

$$\text{Eclo}(q_5) = \{q_3, q_5, q_6\} \quad \text{Eclo}(q_2) = \{q_1, q_2, q_3\}$$

ϵ -Closures

We can resolve the infinite loop issue by keeping the **visited states**:

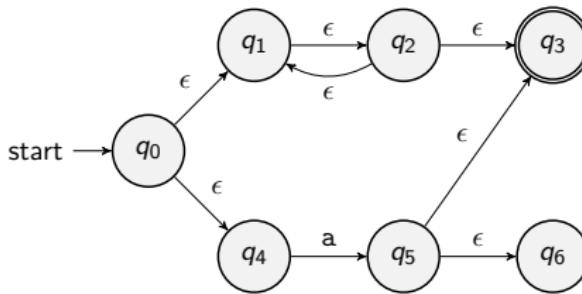

```
case class ENFA(...):
    ...
    // The definitions of epsilon-closures
    def eclo(q: State): Set[State] =
        def aux(rest: List[State], visited: Set[State]): Set[State] = rest match
            case Nil          => visited
            case p :: targets => aux(
                rest      = (trans((p, None)) -- visited - p).toList ++ targets,
                visited   = visited + p,
            )
        aux(List(q), Set())
```

ϵ -Closures

We can resolve the infinite loop issue by keeping the **visited states**:

```
case class ENFA(...):
    ...
    // The definitions of epsilon-closures
    def eclo(q: State): Set[State] =
        def aux(rest: List[State], visited: Set[State]): Set[State] = rest match
            case Nil          => visited
            case p :: targets => aux(
                rest      = (trans((p, None)) -- visited - p).toList ++ targets,
                visited   = visited + p,
            )
        aux(List(q), Set())
```

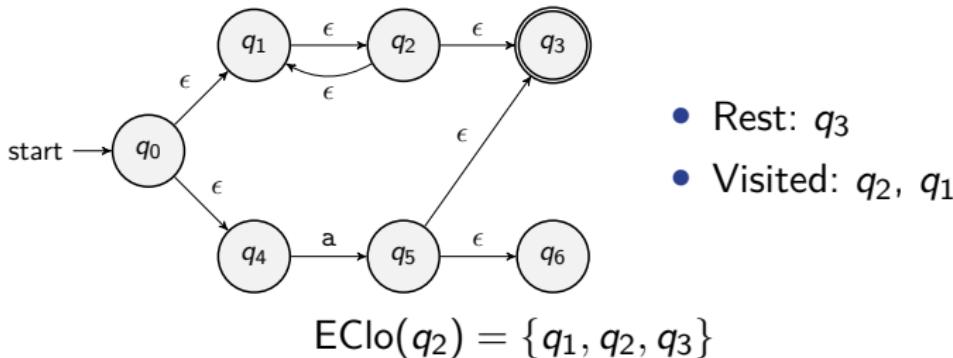

- Rest: q_1, q_3
- Visited: q_2

$$\text{EClo}(q_2) = \{q_1, q_2, q_3\}$$

ϵ -Closures

We can resolve the infinite loop issue by keeping the **visited states**:

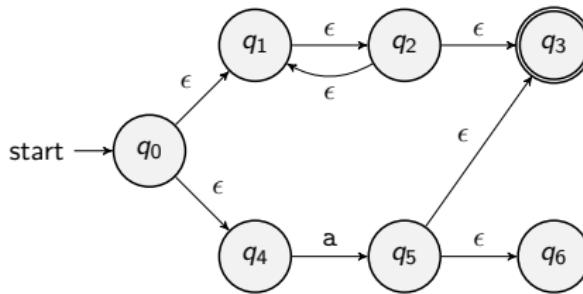

```
case class ENFA(...):
    ...
    // The definitions of epsilon-closures
    def eclo(q: State): Set[State] =
        def aux(rest: List[State], visited: Set[State]): Set[State] = rest match
            case Nil          => visited
            case p :: targets => aux(
                rest      = (trans((p, None)) -- visited - p).toList ++ targets,
                visited   = visited + p,
            )
        aux(List(q), Set())
```

ϵ -Closures

We can resolve the infinite loop issue by keeping the **visited states**:

```
case class ENFA(...):
    ...
    // The definitions of epsilon-closures
    def eclo(q: State): Set[State] =
        def aux(rest: List[State], visited: Set[State]): Set[State] = rest match
            case Nil          => visited
            case p :: targets => aux(
                rest      = (trans((p, None)) -- visited - p).toList ++ targets,
                visited   = visited + p,
            )
        aux(List(q), Set())
```

- Rest:
- Visited: q_2, q_1, q_3

$$\text{EClo}(q_2) = \{q_1, q_2, q_3\}$$

Definition (Extended Transition Function)

For a given ϵ -NFA $N^\epsilon = (Q, \Sigma, \delta, q_0, F)$, the **extended transition function** $\delta^* : \mathcal{P}(Q) \times \Sigma^* \rightarrow \mathcal{P}(Q)$ is defined as follows:

- **(Basis Case)** $\delta^*(S, \epsilon) = \text{EClo}(S)$
- **(Induction Case)** $\delta^*(S, aw) = \delta^*(\bigcup_{q \in \text{EClo}(S)} \delta(q, a), w)$

```
case class ENFA(...):  
  ...  
  
  // The extended transition function of epsilon-NFA  
  def extTrans(qs: Set[State], w: Word): Set[State] = w match  
    case ""      => eclo(qs)  
    case x <| w => extTrans(eclo(qs).flatMap(q => trans(q, Some(x))), w)
```

Language of ϵ -NFA

Definition (Acceptance of a Word)

For a given ϵ -NFA $N^\epsilon = (Q, \Sigma, \delta, q_0, F)$, we say that N^ϵ **accepts** a word $w \in \Sigma^*$ if and only if $\delta^*(q_0, w) \cap F \neq \emptyset$

```
case class ENFA(...):
    ...
    // The acceptance of a word by epsilon-NFA
    def accept(w: Word): Boolean =
        extTrans(Set(initState), w).intersect(finalStates).nonEmpty
```

Definition (Language of ϵ -NFA)

For a given ϵ -NFA $N^\epsilon = (Q, \Sigma, \delta, q_0, F)$, the **language** of N^ϵ is defined as follows:

$$L(N^\epsilon) = \{w \in \Sigma^* \mid N^\epsilon \text{ accepts } w\}$$

Extended Transition Function

Language of ϵ -NFA

2. Equivalence of DFA and ϵ -NFA

DFA \leftarrow ϵ -NFA (Subset Construction)

Theorem (Equivalence of DFA and ϵ -NFA)

A language L is the language $L(D)$ of a DFA D if and only if L is the language $L(N^\epsilon)$ of an ϵ -NFA N^ϵ .

Proof) By the following two theorems.

Theorem (DFA to ϵ -NFA)

For a given DFA $D = (Q, \Sigma, \delta, q, F)$, $\exists \epsilon\text{-NFA } N^\epsilon. L(D) = L(N^\epsilon)$.

Theorem (ϵ -NFA to DFA – Subset Construction)

For a given ϵ -NFA $N^\epsilon = (Q, \Sigma, \delta, q_0, F)$, \exists DFA D . $L(D) = L(N^\epsilon)$.

The formal proofs are exercises for you

Let's see **examples** of the second theorem (DFA \leftarrow ϵ -NFA)

Theorem (ϵ -NFA to DFA – Subset Construction)

For a given ϵ -NFA $N^\epsilon = (Q_{N^\epsilon}, \Sigma, \delta_{N^\epsilon}, q_0, F_{N^\epsilon})$, \exists DFA D . $L(D) = L(N^\epsilon)$.

Proof) Define a DFA

$$D = (Q_D, \Sigma, \delta_D, \text{EClo}(q_0), F_D)$$

where

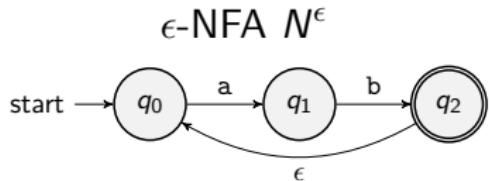

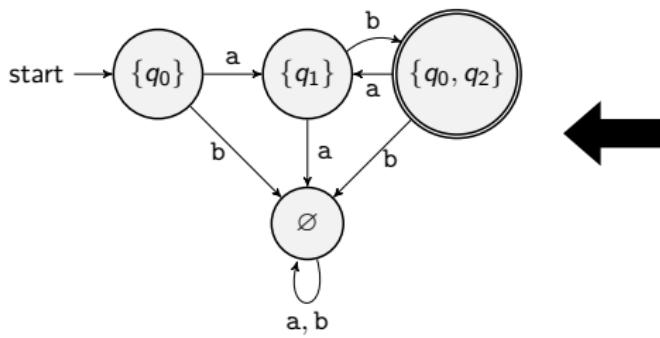

- $Q_D = \{S \subseteq Q_{N^\epsilon} \mid S = \text{EClo}(S)\}$

The states of D are the sets of states of N^ϵ whose **ϵ -closures are themselves** (i.e., $\text{EClo}(S) = S$).

- $\forall S \in Q_D. \forall a \in \Sigma.$

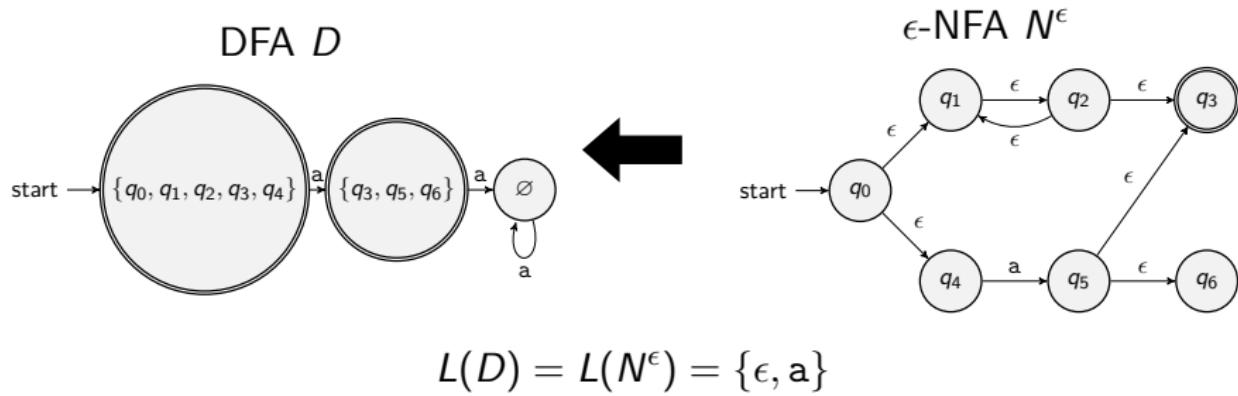

$$\delta_D(S, a) = \text{EClo} \left(\bigcup_{q \in S} \delta_{N^\epsilon}(q, a) \right)$$

- $F_D = \{S \in Q_D \mid S \cap F \neq \emptyset\}$

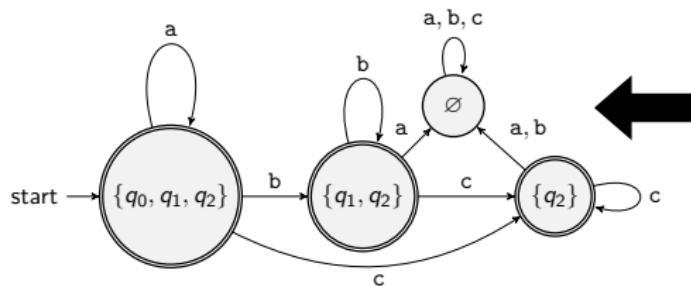

DFA D 

$$L(D) = L(N^\epsilon) = \{(ab)^n \mid n \geq 1\}$$

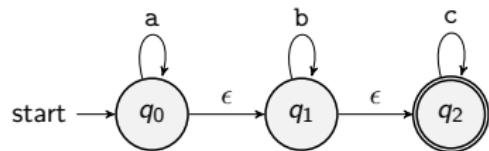

DFA $\leftarrow \epsilon$ -NFA (Subset Construction) – Examples

DFA D

ϵ -NFA N^ϵ

$$L(D) = L(N^\epsilon) = \{a^i b^j c^k \mid i, j, k \geq 0\}$$
